GENERAL INTRODUCTION

This chapter describes the data requirements for estimation of the effects on non target arthropods and plants of a plant protection product and its active substance and how reference values are derived in the EU framework (§1 - §1.5) under [Regulation \(EC\) No 1107/2009](#).

This chapter consists of two parts: a part about non-target arthropods (I) and a part about non-target plants (II).

I NON TARGET ARTHROPODS

1. EU FRAMEWORK

In this document, the procedures for the evaluation and re-evaluation of active substances as laid down in the EU are described; the NL procedure for evaluation of a substance is reverted to when no EU procedure has been laid down. The NL-procedure for the evaluation of a substance is described in §2 - §2.5 of part 2 of the Evaluation Manual (plant protection products). This document aims to give procedures for the approval of active substances and inclusion in [Commission Implementing Regulation \(EU\) No 540/2011](#).

1.1 Introduction

This chapter describes the risk assessment of plant protection products for non-target arthropods.

Non-target arthropods play a vital role in the ecosystem. For this reason plant protection products should cause no unacceptable and prolonged effects on populations of non-target arthropods, not in the treated part and not beyond. An agricultural purpose is served at the same time: the protection of natural enemies in integrated pest control. The risk to non-target arthropods must be assessed in case there is a chance of exposure of these organisms.

Guidelines for the risk assessment for non-target arthropods are given in the [Guidance Document on Terrestrial Ecotoxicology \(Sanco/10329/2002 rev 2 final\)](#) in which the testing procedure is described as elaborated in the report written on the basis of the SETAC/ESCORT 2 workshop [1]

A decision tree with corresponding explanatory notes is presented in Appendix 1. This decision tree summarises the decision scheme for arthropods in non-integrated pest management systems.

Data requirements, evaluation methodologies, criteria and trigger values that deviate from, or further elaborate, the provisions under EU framework (§1), are described under NL framework (§2 - §2.5). The national further provisions can also be used for inclusion of an active substance in [Commission Implementing Regulation \(EU\) No 540/2011](#).

1.2 Data requirements

In order to qualify for inclusion of an active substance in Commission Implementing Regulation (EU) No 540/2011 [2] a dossier that meets the provisions laid down in [Commission Regulation \(EU\) No 283/2013](#) and [Commission Regulation \(EU\) No 284/2013](#) of Regulation (EC) No 1107/2009 must be submitted for the active substance as well as for the product.

Generally, EU and OECD guidelines for the protocol of experiments are mentioned in [Commission Communication 2013/C 95/01](#) and [Commission Communication 2013/C 95/02](#).

When according to the applicant a certain study is not necessary, a relevant scientific

justification can be provided for the non-submission of the particular study.

1.2.1 Data requirements for the active substance

The data requirements regarding the risk of the active substance for non-target arthropods are described in [Commission Regulation \(EU\) No 283/2013](#), point 8.3.2 (Effects on non-target arthropods other than bees).

Point 8.3.2 consists of the following data requirements:

8.3.2.1 Effects on *Aphidius rhopalosiphi*

8.3.2.2 Effects on *Typhlodromus pyri*

1.2.2 Data requirements for the product

The data requirements regarding the risk of the plant protection product for non-target arthropods are described in [Commission Regulation \(EU\) No 284/2013](#), point 10.3.2 (Effects on non-target arthropods other than bees).

Point 10.3.2 consists of the following data requirements:

10.3.2.1 Standard laboratory testing for non-target arthropods

10.3.2.2 Extended laboratory testing, aged residue studies with non-target arthropods

10.3.2.3 Semi-field studies with non-target arthropods

10.3.2.4 Field studies with non-target arthropods

10.3.2.5 Other routes of exposure for non-target arthropods

1.2.3 Data requirements for metabolites

Except for the active substance and the product, data are also required for metabolites to which non-target arthropods may be exposed. Arthropods may be exposed to metabolites in/on plants and to metabolites in the soil. For metabolites in vegetation, standard laboratory tests are normally not required. Metabolites that are the actually active molecule may be exceptions.

General guidance is given in the general part about metabolites as described under 'birds and mammals' (§1.2.3). Where higher tier studies (cage/tent/tunnel or field tests) have been carried out with the pesticide under realistic exposure conditions it can be assumed that the potential risk of metabolites has been taken into account. Soil metabolites: when relevant these are tested with soil meso- and macro-organisms (data point 8.4.2); tests with surface dwelling soil arthropods are therefore not required.

1.3 Risk assessment

The risk assessment methodology for non-target arthropods has in EU context been elaborated in the [Guidance Document on Terrestrial Ecotoxicology \(Sanco/10329/2002 rev 2 final\)](#), which follows the recommendations of the ESCORT 2 workshop [1].

Each study is summarised and analysed separately. The final conclusion and the endpoint per aspect (such as LR_{50}) are presented in a list of endpoints. The risk is assessed against these endpoints.

In Appendix 1 to this chapter, a risk assessment scheme for non-target arthropods in non-integrated pest management systems is included. This decision scheme follows the ESCORT 2 guidance [1], with additions and clarifications such as they have evolved in risk assessment practice over the years. Since these additions and clarifications are in line with what is currently commonly accepted (and required) during EU-reviews, they are included in the EU-part of this chapter. The scheme for integrated pest management systems is included in Appendix 1 to the NL-part of this chapter.

In addition, further elaboration or clarification on risk assessment issues that are used by Ctgb are included in the text below:

Herbicide application to bare soil strips under trees in orchards: in the first tier, foliar dwelling arthropods have to be considered for the treated area. When a risk is identified, refinement is possible by taking into account in-field drift to the grass strips, and performing the refined risk assessment for the foliar dwelling arthropods in the grass strips. The exposure in this scenario should be 10% (due to drift from application to the bare soil beneath the trees).

1.4 Approval

This section describes the approval criteria for active substances (section 1.4.1) and plant protection products (section 1.4.2 and 1.4.3). For the EU approval procedure of active substances a representative formulation has to be included in the dossier. Therefore section 1.4.1 to 1.4.3 apply. For the zonal applications of plant protection products only section 1.4.2 and 1.4.3 apply.

1.4.1 Approval of the active substance

Annex II of [Regulation \(EC\) No 1107/2009](#) provides the procedure and criteria for the approval of an active substances, safeners and synergists.

Point 3 of Annex II of Regulation (EC) No 1107/2009 gives the criteria for the approval of an active substance.

1.4.2 Evaluation of plant protection products

The principles for the evaluation regarding the effects on the environment are presented in [Commission Regulation \(EU\) No 546/2011](#) (i.e. the Uniform Principles). The specific principles for evaluation for non-target arthropods are included in Part B Evaluation, point 2.5.2 Impact on non-target species, point 2.5.2.4.

1.4.3 Decision making for plant protection products

The principles for the decision-making regarding the effects on the environment are presented in [Commission Regulation \(EU\) No 546/2011](#) (i.e. the Uniform Principles). The specific principles for decision making for non-target arthropods are included in Part C Decision making, point 2.5.2 Impact on non-target species, point 2.5.2.4.

1.5 Developments

In March 2010 a follow-up of ESCORT II was organised, the ESCORT III workshop. It is expected that the risk assessment will change on certain points. The report from this workshop is expected to be input for the revision of the Guidance Document on Terrestrial Ecotoxicology (Sanco/10329/2002). This revision is taking place at this moment (by EFSA), and the following EFSA opinion was published on the science behind the upcoming revision: [Scientific opinion addressing the state of the science on risk assessment of plant protection products for non-target arthropods \(EFSA Journal 2015; 13\(2\):3996\)](#) .

II NON TARGET PLANTS

1 EU FRAMEWORK

In this document, the procedures for the evaluation and re-evaluation of active substances as laid down in the EU are described; the NL procedure for evaluation of a substance is reverted to when no EU procedure has been laid down. The NL-procedure for the evaluation of a substance is described in §2 - §2.5 of part 2 of the Evaluation Manual (plant protection products). This document aims to give procedures for the approval of active substances and inclusion in [Commission Implementing Regulation \(EU\) No 540/2011](#).

1.1 Introduction

This chapter describes the risk assessment of plant protection products for terrestrial non-target plants. Terrestrial non-target plants are plants positioned outside the treated field without being a crop.

Terrestrial non-target plants play an important role in the ecosystem. This is why plant protection products should cause no unacceptable and prolonged effects on terrestrial non-target plants. The risk to terrestrial non-target plants must be evaluated if there is a chance of exposure of such plants.

Guidelines for the evaluation of the risk to terrestrial non-target plants are given in the [Guidance Document on Terrestrial Ecotoxicology \(Sanco/10329/2002 rev 2 final\)](#).

The decision tree with corresponding explanatory notes is presented in Appendix 2. These decision trees summarise the decision scheme for terrestrial non-target plants.

Data requirements, evaluation methodologies, criteria and trigger values that deviate from, or further elaborate, the provisions under EU framework (§1), are described under NL framework (§2 - §2.5). The national further provisions can also be used for inclusion of an active substance in [Commission Implementing Regulation \(EU\) No 540/2011](#).

1.2 Data requirements

In order to qualify for inclusion in Commission Implementing Regulation (EU) No 540/2011 [2] a dossier that meets the provisions laid down in [Commission Regulation \(EU\) No 283/2013](#) and [Commission Regulation \(EU\) No 284/2013](#) of Regulation (EC) No 1107/2009 must be submitted for the active substance as well as for the product.

Generally, EU and OECD guidelines for the protocol of experiments are mentioned in [Commission Communication 2013/C 95/01](#) and [Commission Communication 2013/C 95/02](#).

When according to the applicant a certain study is not necessary, a relevant scientific justification can be provided for the non-submission of the particular study.

1.2.1 Data requirements for the active substance

The data requirements regarding the risk of the active substance for non-target plants are described in [Commission Regulation \(EU\) No 283/2013](#), point 8.6 (effects on terrestrial non-target higher plants).

Point 8.6 consists of the following data requirements:

8.6.1: Summary of screening data

8.6.2: Testing on non-target plants

1.2.2 Data requirements for the product

The data requirements regarding the risk of the plant protection product for non-target plants are described in [Commission Regulation \(EU\) No 284/2013](#), point 10.6 (available data from biological primary screening in summary form).

Point 10.6 consists of the following data requirements:

10.6.1: Summary of screening data

10.6.2: Testing on non-target plants

10.6.3: Extended laboratory studies on non-target plants

10.6.4: Semi-field and field studies on non-target plants

1.2.3 Data requirements for metabolites

Standard laboratory tests are normally not required for metabolites. Exceptions may be formed by metabolites that are the actually active molecule. See the general part about metabolites as described in §1.2.3 of Chapter 7 Ecotoxicology; Terrestrial; Birds and mammals for general guidance. Where higher tier studies have been carried out with the pesticide under realistic exposure conditions, it may be assumed that the potential risk of metabolites has been taken into account.

1.3 Risk assessment

The risk assessment methodology for non-target plants has in EU context been elaborated in the [Guidance Document on Terrestrial Ecotoxicology \(Sanco/10329/2002 rev 2 final\)](#).

Each study is summarised and analysed separately. The final conclusion and the endpoint per aspect (such as ER₅₀) are presented in a list of endpoints. Risk is assessed against these endpoints.

In Appendix 2 to this chapter, a risk assessment scheme for non-target terrestrial plants is included.

There are a few issues which need some more explanation, because it is not described clearly in the Guidance Document on Terrestrial Ecotoxicology:

- *Use of MAF*

In the [EFSA technical report: Outcome of the pesticides peer review meeting on general recurring issues in ecotoxicology, December 2015](#), the following is agreed regarding the use of a MAF in the risk assessment for Non-target Terrestrial Plants. Note that this is only valid for EU assessments (DAR/RAR):

It was agreed that, from a scientific point of view, there is a logical reason to account for multiple applications in the risk assessment for NTTP. There were various approaches as to how this could be considered (i.e. foliar or soil default values of ESCORT II or EFSA PPR Panel (2014)). However, the experts could not agree which approach should be applied to the risk assessment and it was noted that currently different MAF values were being used by different RMS's (i.e. no harmonised approach). Therefore, it was agreed that for the risk assessment of active substances, no MAF values should be used by default, until a guidance document is developed.

- *Species Sensitivity Distribution: Acceptability criteria HC5*

If an SSD is run, the data normality must be accepted at no less than 0.05 significance level to be acceptable for use in RA (look under “goodness-of-fit”). Modelling which does not pass at least this level (i.e. only passes at 0.025 or 0.01) indicates a poor fit for the

data and a less reliable outcome¹. This also in line with the current agreement in the draft NTP guidance.

Further elaborations of the EU evaluation methodology:

Combination toxicity

Combination toxicity must be determined when plant protection products contain several active substances. The issue of combined toxicity is further described in Appendix A.

1.4 Approval

This section describes the approval criteria for active substances (section 1.4.1) and plant protection products (section 1.4.2 and 1.4.3). For the EU approval procedure of active substances a representative formulation has to be included in the dossier. Therefore section 1.4.1 to 1.4.3 apply. For the zonal applications of plant protection products only section 1.4.2 and 1.4.3 apply.

1.4.1 Approval of the active substance

Annex II of [Regulation \(EC\) No 1107/2009](#) provides the procedure and criteria for the approval of an active substances, safeners and synergists. Point 3 of Annex II of Regulation (EC) No 1107/2009 gives the criteria for the approval of an active substance.

1.4.2 Evaluation of plant protection products

The evaluation, as applied for the risk assessment for non-target plants, has been elaborated in the [Guidance Document on Terrestrial Ecotoxicology \(Sanco/10329/2002 rev 2 final\)](#).

1.4.3 Decision making for plant protection products

Decision making, as applied in the risk assessment for non-target plants, has been elaborated in the [Guidance Document on Terrestrial Ecotoxicology \(Sanco/10329/2002 rev 2 final\)](#).

1.5 Developments

Revision of the [Guidance Document on Terrestrial Ecotoxicology \(Sanco/10329/2002 rev 2 final\)](#) is taking place at this moment (by EFSA), and the following EFSA opinion was published on the science behind the upcoming revision: [Scientific Opinion addressing the state of the science on risk assessment of plant protection products for non-target terrestrial plants \(EFSA Journal 2014; 12\(7\): 3800\)](#).

¹ As the significance level decreases (and the critical value increases), it becomes less and less probable that the sample derives from a normal distribution.

3 APPENDICES

Appendix 1 Explanatory notes decision tree risk to non-target arthropods	12
Appendix 2 Explanatory notes decision tree risk to terrestrial non-target plants	18

Appendix 1 Explanatory notes decision tree risk to non-target arthropods

- 1) A distinction is made between integrated and non-integrated pest management systems because the evaluation for non-target arthropods for these two types of systems is essentially different. In the case of integrated pest management systems natural enemies are deliberately brought into the cropping system to control pests. In the case of non-integrated pest management systems the risk is estimated for non-target arthropods that are present by nature. The scheme for non-integrated systems is dealt with in this chapter. The scheme for integrated pest management systems is included in Appendix 1 to the NL-part of this chapter.
- 2) The applicant should always submit data about the risk to non-target arthropods if there is a chance of exposure of these organisms (question 283/2013 8.3.2 and 284/2013 10.3.2). In case of applications on the soil and on crops there is practically always chance of exposure. It should be noted that some species have overwintering larvae in the soil, which, if relevant, must be taken into account in the risk assessment as well. The chance of exposure is low in case of application of products for sealing and healing of pruning wounds.
- 3) The first step consists of the performance of glass plate tests with the standard test organisms *Aphidius rhopalosiphi* and *Typhlodromus pyri*, preferably dose-response tests so that an LR50 value can be established. When, however, a low toxicity is expected, limit tests can also be carried out with a dose that is equal to the maximum use dose multiplied by the Multiple Application Factor (MAF). These tests should normally be carried out with the formulation. For determination of the MAF reference is made to the ESCORT 2 report [1].
- 4) The standard species mentioned above are not suitable for formulations such as granules, seed dressings, baits and IGRs (Insect Growth Regulators) in view of:
 - technical reasons: laboratory glass plate tests with the two standard species cannot be carried out with granular formulations, seed dressings and baits;
 - the fact that effects cannot be detected in a standard laboratory test with the standard species as result of a different mode of action (e.g. an acute laboratory test with an Insect Growth regulator (IGR) on *A. rhopalosiphi* will probably not show any effect).

The approach described in the [Guidance Document on Terrestrial Ecotoxicology \(Sanco/10329/2002 rev 2 final\)](#) is followed for these types of products:

- for products which are applied into the soil (e.g. granules, seed dressings, baits) studies should be carried out with *Hypoaspis aculeifer* or *Folsomia candida*. When considered suitable, studies can be carried out with *Aleochara sp.* (N.B. test compound should be mixed into the soil).
- For products which are applied on (bare) soil, tests with several soil (surface) dwelling species are acceptable (e.g. *Hypoaspis aculeifer*, *Folsomia candida*, *Aleochara bliineata*, *Poecilus cupreus*, *Pardosa sp.*).
- For IGRs and other plant protection products with a special mode of action the tests should be concentrated on those stages of non-target arthropods that are sensitive to the plant protection product in question (e.g. juvenile stages) while taking relevant absorption routes into account. Tests must be carried out with *Typhlodromus pyri* and one other species (e.g. *Coccinella septempunctata*, *Orius laevigatus* or *Chrysoperla carnea*).

There are several examples of special applications such as drenching treatments, application via drip irrigation, etc. Such cases should be dealt with pragmatically, which means that it should be considered case by case which types of organisms are exposed and in which way the test can be conducted.

Except for the active substance and the product, data are also required for metabolites to which non-target arthropods may be exposed. Arthropods may be exposed to metabolites in/on plants and to metabolites in the soil. For metabolites in vegetation standard laboratory tests are normally not required. Metabolites that are the actually active molecule may be exceptions. General guidance is given in the general part about metabolites as described under 'birds and mammals'.

Where higher tier studies (cage/tent/tunnel or field tests) have been carried out with the pesticide under realistic exposure conditions it can be assumed that the potential risk of metabolites has been taken into account.

Soil metabolites are tested with soil organisms; tests with surface dwelling soil arthropods are therefore not required.

- 5) A Hazard Quotient (HQ) must be calculated for both standard species and both the 'in-field' risk as well as the 'off-field' risk are taken into account. For the method according to which the 'in-field' and 'off-field' exposure must be calculated we refer to the Guidance Document on Terrestrial Ecotoxicology, on the understanding that for national risk assessments NL-specific drift figures are used for calculating the 'off-field' exposure, for which we refer to §2.3 (NL-part).

Note on correction factor 0.5 from ESCORT 2 for the in field exposure calculation for orchards and vineyards:

- This correction factor can be used in the exposure calculation for the HQ when the effect endpoint is based on a 2D-test (i.e. glass plate or leaf disc). If the test is in a '3D-system', i.e. spraying of whole plants, the correction factor is not applicable.
- This factor can only be used for orchards and vineyards (but not other '3D crops' such as e.g. tomatoes).

The criterion for both HQ values is that these should be lower than 2 (or effects in limit tests <50%). This criterion is based on available (semi-) field data where lethal, sublethal and reproduction endpoints have been measured for a considerable number of types of substances and species. This means that this first step in the evaluation (in which the criterion $HQ < 2$ is applied) also covers sublethal and reproduction effects and it is not necessary to separately consider sublethal and reproduction endpoints in the first step of the evaluation.

Where also other species than *Aphidius rhopalosiphi* and *Typhlodromus pyri* have been tested in first tier laboratory tests, these cannot be tested against the HQ trigger of 2 because this trigger has only been validated for *Aphidius* and *Typhlodromus*. The results of these tests will be assessed against the criterion of 50% effect (or HQ of 1, if LR50 and ER50 values are available).

When it concerns tests with the soil organisms *Hypoaspis aculeifer* and *Folsomia candida*, the NOEC (mg/kg soil) is the relevant endpoint. For risk assessment a safety factor of 5 is applied. In the case that artificial soil is used in the test, correction for the percentage of organic matter is necessary (if $\log K_{ow} > 2$).

Off-crop interception:

In cases that only exposure of soil dwelling species is relevant (for example when a reasoned case is made that soil surface spiders are the most sensitive species), interception by the off-crop vegetation may be taken into account in the off-field risk assessment.

For the time being the following interception percentages are applied - till better underpinned percentages come available - which are considered realistic worst-case:

- December – February: 20%
- March: 30%
- April: 40%
- May – September: 50%
- October: 40%

It should be noted that when these percentages are taken into account, the vegetation distribution factor cannot be used in the HQ-calculation (off-field).

- 6) Where the HQ values are ≥ 2 and suitable or desirable risk reduction measures 'in-field' and/or 'off-field' are not possible, higher tier tests must be carried out. First, the sensitive species for which the HQ value is ≥ 2 should be studied in such a higher tier test where extra species are tested: in case that only the HQ for the 'in-field' risk estimate is exceeded, one extra species must be tested; in case the HQ for 'in-field' as well as 'off-field' is exceeded, two extra species. The preferred species are: *Orius laevigatus*, *Chrysoperla carnea*, *Coccinella septempunctata* and *Aleochara bilineata* in view of the fact that the available data indicate that these organisms are relatively sensitive and that good test methods are available. The species *Aleochara bilineata* should in any case be used for products that are applied early in the season and where products are applied on the soil.

Higher tier tests concern extended laboratory tests (with natural substrate) and (semi) field tests. 'Aged-residue' tests also come under the higher tier tests. These tests can be used for establishing the duration of the effect in view of the possible recovery of populations by recolonisation. See also note 7) below.

If the only available data are extended laboratory tests with *A. rhopalosiphi* and *T. pyri*, tests with two additional species will be required, irrespective of the acceptability of the risk for *A. rhopalosiphi* and *T. pyri*. The reason for this is that in this case no first tier risk assessment can be performed to establish the requirements for additional species.

It should be noted that generally, in-crop field studies are considered not acceptable to address off-crop risks. When a field study is chosen as approach to address the off-crop risk to non-target arthropods, it should be demonstrated in this study that no unacceptable effects on a non-target arthropod community that is representative for fauna of off-crop habitats in The Netherlands (e.g. meadow, hay field or (agricultural) verge) will occur as a result from drift exposure. Studies conducted in e.g. Northern France and Germany are also considered representative for The Netherlands. Preferably a multi-dose rate (NOEC) design is used. Before such a study is undertaken, the study protocol may be discussed with the Ctgb.

If an in-crop field test is performed to address an in-crop risk, and *A. rhopalosiphi* and *T. pyri* do not occur in the crop of concern, it is acceptable that these species are not present in the study, as long as a representative fauna for this crop is present.

Further guidance on the evaluation of arthropod field studies can be found in De Jong et

al. (2010) (Guidance for summarising and evaluating field studies with non-target arthropods. RIVM report 601712006/2010).

For 'in-field' and 'off-field' the following risk reducing measures are among the options:

'in-field':

- reduction of the dose level;
- changes in application frequency and application interval;
- changes in timing of the application.

'off-field':

- measures that reduce the amount of drift to the area outside the crop such as:
 - . buffer zones;
 - . wind hedges;
 - . drift-reducing application techniques.

- 7) The risk is unacceptable if the effects found in the extended laboratory tests are equal to or higher than the trigger value (trigger value is 50%²) and there is no potential (rapid) recovery or recolonisation. When risk-mitigating measures neither lead to an acceptable risk to non-target arthropods, the product cannot be authorised.

The criterion for (potential) recovery or recolonisation for 'in-field' is that this must be the case before the following spraying season. The period for 'off-field' is shorter, for the time being without a specific definition. The [Guidance Document on Terrestrial Ecotoxicology \(Sanco/10329/2002 rev 2 final\)](#) mentions an ecologically relevant period. It should be noted however, that under the new data requirements, aged residue tests can no longer be used for the off-field risk assessment. This means that for the off-field risk assessment, off-field field studies demonstrating no effects or actual recovery should be provided. Ctgb is of the opinion that the 'ecologically relevant period' should be very short, because the off-crop area is important for recolonisation of species into the in-field area. Hence, a relatively undisturbed off-crop area is necessary to make recolonisation possible (recolonisation of the in-field area from the off-crop area can cause source-sink effects, which is an additional stress-factor tot the off-crop area).

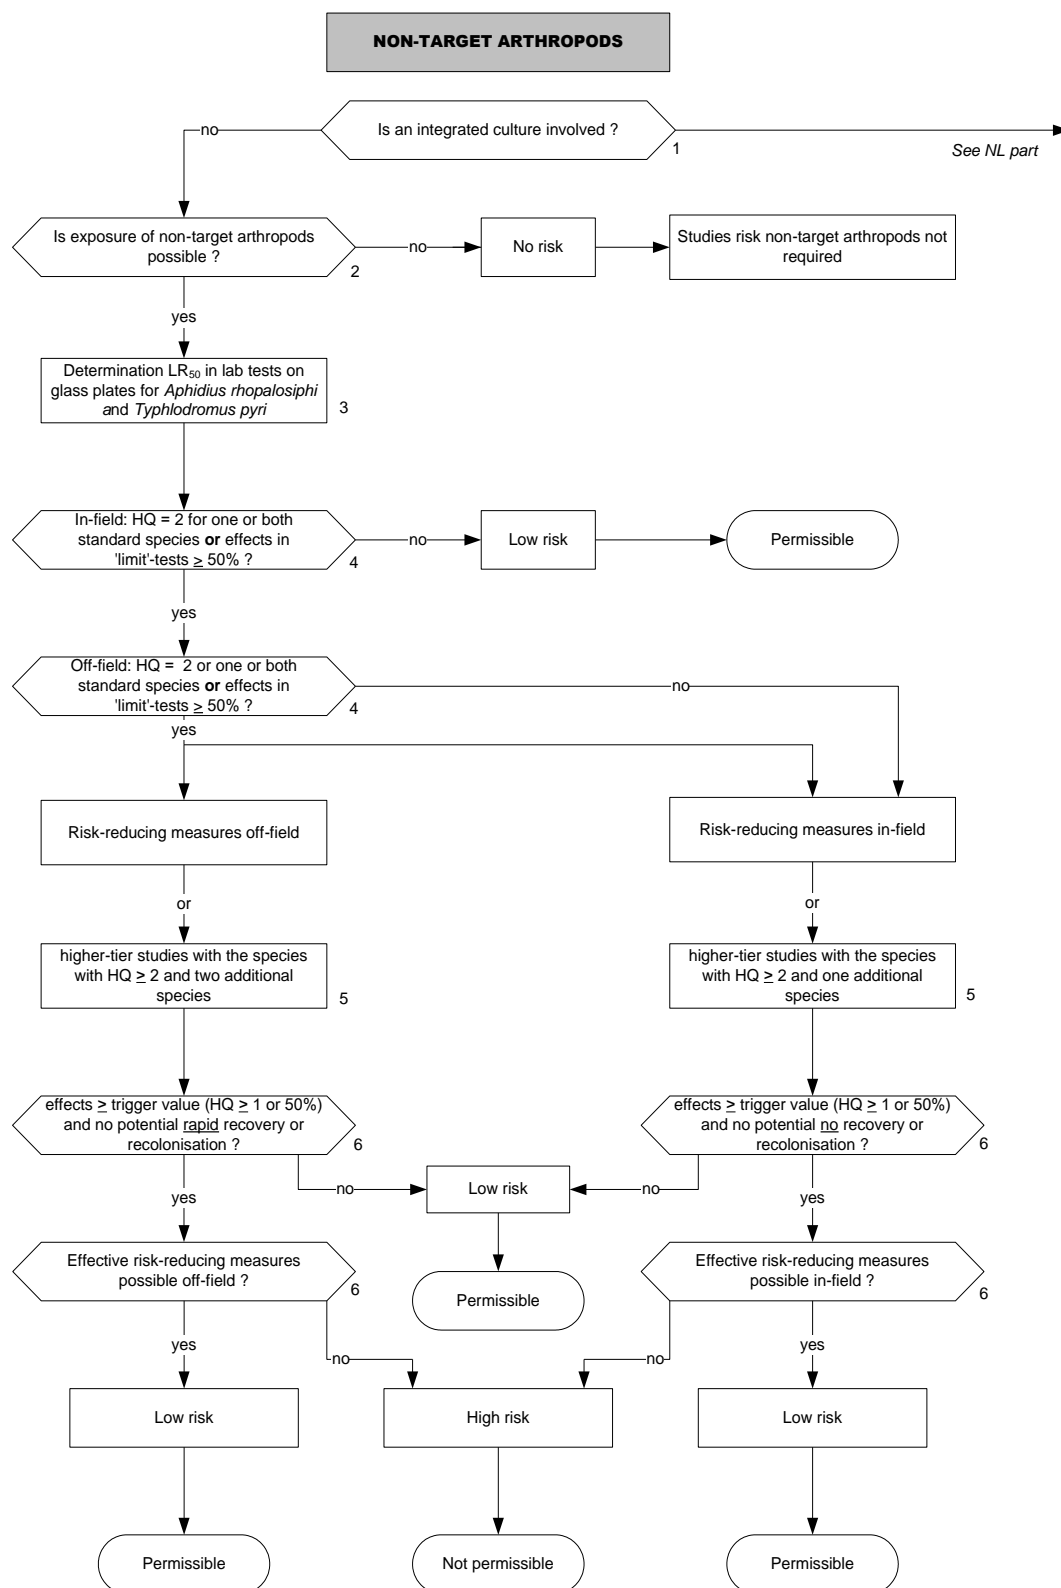

For field tests, ESCORT 2 does not provide fixed trigger values for acceptability of effects. As clear guidance on the use of the endpoints from this type of studies is currently lacking, the recommendation in the proceedings from the ESCORT 3 workshop (2010) is followed for the off-field risk assessment:

At the level of field studies, the no observed effect rate (NOER) community and the no observed ecologically adverse effect rate (NOEAER) population (effects of limited magnitude and duration) should be used for the off-field risk assessment.

To further specify 'effects of limited magnitude and duration', Ctgb considers this to be 'slight and transient effects' cf. Effect Class 2 in the Guidance for summarising and evaluating field studies with non-target arthropods (De Jong et al. , 2010) [2], taking into account what is said above about the duration of the ecologically relevant period. In De Jong et al. (2010), Class 2 effects are defined as: Quantitatively restricted response of one or a few taxa and only observed on one sampling occasion.

² The trigger value of 50% can be considered equal to an HQ value of 1, provided that only mortality effects occur and no sublethal effects. In case sublethal effects are found, ER50 can be determined and tested against the HQ trigger of 1.

For the in-field risk assessment, if in- field field studies are available, recovery before the start of the next spraying season should be demonstrated. This applies to Effect Class 6 or lower from de Jong et al. (2010).

Appendix 2 Explanatory notes decision tree risk to terrestrial non-target plants

- 1) Definition: terrestrial non-target plants are plants positioned outside the field to be treated without being a crop.
- 2) Data on the risk to terrestrial non-target plants are not always required. Where exposure is negligible, no data need to be submitted, e.g., in the case of:
 - Rodenticides
 - Seed treatments
 - Granules
 - Bulb dipping
 - Drenching treatment
 - Substances used to cover and cure pruning wounds
 - Substance that are used in stored products

- 3) This step is based on the already available data, with a preference for screening data. Data on at least 6 species of different taxa tested with the highest nominal dose (1x) should be available. These species should cover monocotyledonous as well as dicotyledonous species. Besides these data, further information available in the biological dossier or obtained from various field experiments such as efficacy studies, residue studies, environmental-behavioural and ecotoxicological studies about efficacy, selectivity, phytotoxicity etc. can be provided.
This first step can be skipped for herbicides and plant growth regulators because these substances will as result of their envisaged effect on plants always reach the second step.

The criterion is that the risk can be considered as acceptable where no data indicate that one or more species experience more than 50% phytotoxic effects at the maximum dose level. If the results show that there is more than 50% effect for one species or that there are clear indications of effects on more than one species, additional research needs to be carried out.

- 4) Where a potential risk is identified (more than 50% effect for one or more species at the maximum dose), specific information must be submitted about the toxicity of the substance for terrestrial plants. These are laboratory experiments on a selection of plants. It is strongly recommended to conduct dose-response tests with 6 –10 plant species representing families for which significant herbicidal effect is claimed.
These tests should resemble realistic exposure conditions as much as possible. For applications on leaves, e.g., the tests must be carried out by spraying the pesticide on the plant. Application on soil should be carried out where this is more suitable in view of the mode of action.

Tests must be carried out with the formulations.

Suitable test protocols are available: OECD guideline 208 (Seedling emergence and seedling growth test) and OECD guideline 227 (Vegetative vigour test).

- 5) This step consists of a quantitative risk assessment according to the exposure/effect approach. Exposure as well as effect are expressed in application dose (g/ha). ER50 values (ER50 = the dose at which 50% effect is observed) are available from the plant tests as mentioned under step 2 of the data requirements. There are two possible approaches for the risk assessment: the deterministic approach and the probabilistic approach. The most suitable approach depends on the dataset.

Deterministic approach

In the deterministic approach the toxicity of the most sensitive species is taken as starting point for the effect. Where the ratio toxicity/exposure is higher than 5, the risk is considered acceptable. This trigger value of 5 is valid where data on at least 6 plant species are available. In case data on significantly more than 6 plant species are available, this trigger value may –where appropriate – be adjusted slightly upward (expert judgement).

Probabilistic approach

Probabilistic methods in which the 'species sensitivity distribution' (SSD) is used may in principle be applied because data on 6 – 10 species are available. This approach requires a log-normal or a differently defined type of distribution of the data. If a SSD is run, the data normality must be accepted at no less than 0.05 significance level to be acceptable for use in RA (look under "goodness-of-fit"). Modelling which does not pass at least this level (i.e. only passes at 0.025 or 0.01) indicates a poor fit for the data and a less reliable outcome³. This also in line with the current agreement in the draft NTP guidance. In case the ER50 for at least 95% of the species (HR5) is above the highest estimated exposure level, the risk to terrestrial non-target plants is considered acceptable. If not, the risk is high.

The initial exposure of non-target plants should be determined at the following distances from the centre of the last crop row:

- field crops (including "soft fruit" and bush and hedge shrubbery) and soil applications, as in the case of herbicides: 2 m (1 m from the edge of the parcel) (evaluation zone 1.5 – 2.5 m);
- 3 m for large fruit (evaluation zone 2.5 – 3.5 m);
- 5 m for lane trees (evaluation zone 4.5 – 5.5 m).

For these distances the following drift percentages apply in the Netherlands:

- outdoor field cultures and soil applications: 4.7%;
- large fruit: 37% before 1 May; 15.9% after 1 May (the latter value (15.9%) is also used for grapes and small fruit (irrespective of application time).;
- lane trees: high lane trees: 11.9%; spindle trees ('spillen') (closely spaced): 1.8% and transplanted trees ('opzetters') (widely spaced): 6.3%. These percentages are in case of a crop-free zone of 5 m (LOTV)).

Where the crop free zones exceed the standard distances from the centre of the last crop row mentioned here, the 'off-field' area only starts after the crop-free zone and the drift percentage must be determined at a distance as large as the crop-free zone.

Where natural objects have been placed to reduce the amount of drift (e.g. a wind hedge) this object should not be considered as part of the off-field area that needs to be protected. It must be kept in mind that those crop-free zones and natural objects in many cases are only applied on those parts of parcels which borders watercourses. Protection

³ As the significance level decreases (and the critical value increases), it becomes less and less probable that the sample derives from a normal distribution.

of non-target terrestrial plants is needed for all sides of a parcel.

In cases that only exposure by the soil is relevant (e.g. when an active substance has only adverse effects on pre-emergence stadia of non-target plants), some interception by the off-crop vegetation may be taken into account. For the time being the following interception percentages are applied - till better underpinned percentages come available - which are considered realistic worst-case:

- December – February: 20%
- March: 30%
- April: 40%
- May – September: 50%
- October: 40%

If a plant protection product contains several active substances, the combination toxicity must be determined as well as for combinations of plant protection products of which the combination (tank mix) is recommended in the directions for use.

For the acute risk assessment, the combination toxicity on the basis of the tests with the product are compared with the combination toxicity on the basis of toxicity research with the separate active substances. The risk of combination products is determined on the basis of the lowest TER as calculated based on the toxicity of the separate active substances or the toxicity of the product.

The combination toxicity is determined on the basis of concentration addition. For the calculation method see Appendix A.

- 6) Where on the basis of the previous step a high risk is concluded to exist, the use is not permissible unless it can be demonstrated by means of adequate risk evaluation that there are no unacceptable direct or indirect effects for terrestrial non-target plants.

An adequate risk evaluation may consist of the performance of a (semi) field study to investigate the effects on non-target plants under realistic application conditions. Because such studies take a long time and are expensive, it is recommended to investigate whether options exist for refinement of the exposure and/or effects. In addition, (semi) field studies are not required if the risk identified in step 2 can sufficiently be reduced by means of risk-mitigating measures.

Field and semi-field studies with non-target plants have not been standardised. It is therefore recommended to contact the Ctgb beforehand to discuss the protocol. Generally, it can be stated that in such tests effects on plant abundance and biomass production at different distances from the crop or at exposure levels representing exposure at different distances from the crop, need to be analysed.

Because the exposure of terrestrial non-target plants is mainly caused by drift of pesticides, possible measures to reduce the risk to these plants are based on reduction of the amount of drift. In principle, all already existing drift-mitigating measures can be applied. The drift reduction of drift reducing measures, which are easy to realise in practice are mentioned in paragraph 2.3 of the NL part.
